

Note: Problem 1 uses C++ 11 standard and VS 2015 to compile.

1. The Buddy System Code shows as figure 1.1, 1.2 shows

```
/** allocate memory to process */
bool Allocate(pair<string, int> &input, Node* root, Node* node, unordered_map<string, Node*> &map, list<Node*> &set) {
    int size = calculate(input.second);
    Node* temp = node;
    while (temp->get_Val() > size) {
        int split_value = temp->get_Val() / 2;
        temp->set_Flag(true);
        Node* left = new Node(split_value);
        Node* right = new Node(split_value);
        temp->set_Left(left);
        temp->set_Right(right);
        left->set_Father(temp);
        right->set_Father(temp);
        left->set_Brother(right);
        right->set_Brother(left);
        list<Node*>::iterator it = set.begin();
        for (it; it != set.end(); ++it)
            if ((*it) == temp)
                break;
        temp = temp->get_Left();
        set.insert(it, left);
        set.insert(it, right);
        set.erase(it);
    }
    temp->set_Allocate(input.second);
    temp->set_Flag(true);
    map[input.first] = temp;
    return true;
}
```

Figure 1.1

```
/** release memory of process */
bool Release(pair<string, int> &input, Node* root, Node* node, unordered_map<string, Node*> &map, list<Node*> &set) {
    Node* temp = map[input.first];
    temp->set_Allocate(0);
    temp->set_Flag(false);

    if (node == root) {
        root->set_Allocate(0);
        root->set_Flag(false);
    }

    while (temp->get_Brother()->get_Flag() == false) {
        Node* child_1 = temp;
        Node* child_2 = temp->get_Brother();
        list<Node*>::iterator it_child1 = set.begin();
        list<Node*>::iterator it_child2 = set.begin();
        for (it_child1; it_child1 != set.end(); ++it_child1)
            if ((*it_child1) == temp)
                break;
        for (it_child2; it_child2 != set.end(); ++it_child2)
            if ((*it_child2) == temp->get_Brother())
                break;
        temp = temp->get_Father();
        temp->set_Allocate(0);
        temp->set_Flag(false);
        set.insert(it_child1, temp);
        set.erase(it_child1);
        set.erase(it_child2);
        delete child_1;
        delete child_2;
        if (set.size() == 1)
            break;
    }
    return true;
}
```

Figure 1.2

The Buddy System output table shows as follows:

```

input A with value 20
The start address is: 0 32 64 128 256 512 1024
The end address is: 32 64 128 256 512 1024 2048
The block size is: 32 32 64 128 256 512 1024
The allocation is: 20 0 0 0 0 0 0

input B with value 35
The start address is: 0 32 64 128 256 512 1024
The end address is: 32 64 128 256 512 1024 2048
The block size is: 32 32 64 128 256 512 1024
The allocation is: 20 0 35 0 0 0 0

input C with value 90
The start address is: 0 32 64 128 256 512 1024
The end address is: 32 64 128 256 512 1024 2048
The block size is: 32 32 64 128 256 512 1024
The allocation is: 20 0 35 90 0 0 0

input D with value 40
The start address is: 0 32 64 128 256 320 384 512 1024
The end address is: 32 64 128 256 320 384 512 1024 2048
The block size is: 32 32 64 128 64 64 128 512 1024
The allocation is: 20 0 35 90 40 0 0 0 0

input E with value 240
The start address is: 0 32 64 128 256 320 384 512 768 1024
The end address is: 32 64 128 256 320 384 512 768 1024 2048
The block size is: 32 32 64 128 64 64 128 256 256 1024
The allocation is: 20 0 35 90 40 0 0 240 0 0

input A with value -20
The start address is: 0 64 128 256 320 384 512 768 1024
The end address is: 64 128 256 320 384 512 768 1024 2048
The block size is: 64 64 128 64 64 128 256 256 1024
The allocation is: 0 35 90 40 0 0 240 0 0

input B with value -35
The start address is: 0 128 256 320 384 512 768 1024
The end address is: 128 256 320 384 512 768 1024 2048
The block size is: 128 128 64 64 128 256 256 1024
The allocation is: 0 90 40 0 0 240 0 0

input C with value -90
The start address is: 0 256 320 384 512 768 1024
The end address is: 256 320 384 512 768 1024 2048
The block size is: 256 64 64 128 256 256 1024
The allocation is: 0 40 0 0 240 0 0

input D with value -40
The start address is: 0 512 768 1024
The end address is: 512 768 1024 2048
The block size is: 512 256 256 1024
The allocation is: 0 240 0 0

input E with value -240
The start address is: 0
The end address is: 2048
The block size is: 2048
The allocation is: 0

```

2.

9	11	12
0	9	20
		32

Because the page table field are $9+11 = 20$. The offset is $32 - 20 = 12$.

Thus, the page size is $2^{12} \text{ B} = 4\text{KB}$.

The number of pages size are 2^{20}

3. The page reference string is (3, 15, 3, 19, 3, 8, 19, 3, 3, 3) or (3, 15, 3, 19, 3, 8, 19, 3, 3, 3, 9)

Condition: PC = 2020, SP = 10192, page size = 512B, instruction size = 4B

PC	Operation	Reference Pages
2020	Load word 8118 (a value of a procedure input parameter) into register 0	PC: $2020/512 = 3$ Data: $8118/512 = 15$

2024	Push register 0 onto the stack	PC: 2024/512 = 3 Stack: 10192/512 = 19 SP: 10192 - 4 = 10188
2028	Call a procedure at 4120 (the return address is stacked)	PC: 2028/512 = 3 Data: 4120/512 = 8 Stack: 10188/512 = 19
2032	Remove one word (the actual parameter) from the stack and	PC: 2032/512 = 3
2036	Compare the actual parameter to constant 7	PC: 2036/512 = 3
2040	If equal, jump to 5000	PC: 2040/512 = 3 Data: 5000/512 = 9 (depend on whether the matching is equal)

4.

1) Explain the value and drawbacks of “non-traditional” hardware architectures for supporting virtual memory (i.e., *inverted page table* and *TLB-only*).

TLB:

Value:

- a. TLB with high hit ratio will save significant time of finding a page.

Drawbacks:

- a. TLB size is not enough for memory-intensive.
- b. TLB is expensive
- c. Increase the page size of TLB will reduce time but results fragments of some application do not need so much space.

Inverted Page Tables:

Value:

- a. Inverted Page Tables reduce the amount of physical memory need to track virtual-to-physical address translations.

Drawbacks:

- a. The Inverted Page Tables do not contain complete information about the logical address space of a process, and that information is required if a referenced page is not currently in memory will cause page faults.
- b. Inverted Page Tables may need external page tables may negate the utility of inverted tables because page faults consistently generated by the requirement of a process.

2)

The physical page number of process 1 are 4, 2, 0.

Process ID	Page number	Physical page frame
1	0	4
1	1	2
1	2	0

5.

1) MRU

MRU will result in $3(l+1)$ page faults with the string $\omega = (1,2,3)^k (4,5,6)^l$

Proof: MRU is the Most Recently Used page replacement which will replace the page most recently used page out.

1	2	3	... k-1 times ...	4	5	6	... l-1 times ...
1	1	1	1	1	1	1	1
	2	2	2	2	2	2	2
		3	3	4	5	6	(4,5,6....)
F	F	F		F	F	F	F....F

From this table, when CPU want page 4,5,6, it always not in the block and always is replaced to the block. Thus, the faults time is $3 \cdot l$. When page 1, 2, 3 come in the memory, there are 3 times faults. Consequently, the total faults times of MRU are $3 \cdot (l + 1)$.

2) LFU

LFU will result in $3[\min(k,l)+1]$ page faults

Proof: LFU is Least Frequency Used page replacement which will replace the Least frequency used page out.

1	2	3	... k-1 times ...	4	5	6	... k-2 times ...	(K)th			$l-k > 0$
1	1	1	1	4	5	6	4,5,6	4	4	4	4
	2	2	2	2	2	2	2	2	5	5	5
		3	3	3	3	3	3	3	3	6	6
F	F	F		F	F	F	F....F	F	F	F	

From this table, the page 1,2,3 enter the block cause 3 times page faults. Then, before page 4,5,6 coming, page 1, 2, 3's count are k times. If $l \leq k$, the 4,5,6's count are less than k, then they will be replaced by l times which means the there will be $3 \cdot l$ page faults. If $l > k$, the page 4,5,6's count are larger than k which means there will be k times page faults. Thus, the total page faults are $3 \cdot [\min(k, l) + 1]$.

3) FIFO

FIFO will result in 6 page faults.

Proof: FIFO is First In First Out which means first page in the memory will be replaced out.

1	2	3	... k-1 times ...	4	5	6	... l-1 times ...
1	1	1	1	4	4	4	1
	2	2	2	2	5	5	2
		3	3	3	3	6	(4,5,6....)
F	F	F		F	F	F	

From this table, the page 1,2,3 cause 3 page faults at first and page 4,5,6 cause another 3 page faults when they come in. Thus, the total page faults is 6.

4) LRU

LRU will result in 6 page faults.

Proof, LRU is Least Recently Used replacement which means it will replace the recently used pages out.

1	2	3	... k-1 times ...	4	5	6	... l-1 times ...
1	1	1	1	4	4	4	1
	2	2	2	2	5	5	2
		3	3	3	3	6	(4,5,6....)
F	F	F		F	F	F	

From this table, the page 1,2,3 cause 3 page faults at first and page 4,5,6 cause another 3 page faults when they come in at first. Thus, the total page faults is 6.
